**Abstract.** *Background/Aim: Huaier extract, whose main active constituent is the proteoglycan, has anti-tumor activity in several types of malignancies. In this study, we aimed to elucidate the effect of Huaier extract in hepatoblastoma cells. Materials and Methods: The effect of Huaier extract on the proliferation of human hepatoblastoma cell lines HepG2 and HuH-6, was examined. Results: Incubation with Huaier extract resulted in a marked, dose-dependent decrease in hepatoblastoma cell viability. Huaier extract induced S phase arrest in hepatoblastoma cells and upregulated the expression of the cell cycle related proteins cyclin D1 and cyclin D3. It also induced apoptosis in hepatoblastoma cells. Additionally, it significantly suppressed the activity of p-ERK and p-MEK. Conclusion: Huaier extract inhibits proliferation, and induces cell apoptosis and cell cycle arrest via the MEK-ERK pathway in hepatoblastoma cells. Huaier extract may act as a complementary agent for treating hepatoblastoma.*

Hepatoblastoma is the most common childhood malignant liver tumor. The incidence peaks in the first two years of life, with the majority of cases presenting by the 5<sup>th</sup> year of age (1). Complete surgical resection is the mainstay of therapy for hepatoblastoma. Unfortunately, a large number of cases are unresectable at presentation either because they are too large, or multifocal, or due to the close proximity to major vascular structures. This led to a universally gloomy prognosis before neoadjuvant chemotherapy became the standard of care in the treatment of hepatoblastoma (2).

**Key Words:** Hepatoblastoma, MEK/ERK, Huaier extract, apoptosis.

Therefore, identification of novel antitumor agents from natural products is an alternative choice for the management of hepatoblastoma.

In recent years, many Chinese herbs have been gradually discovered to be potential sources of antitumor drugs killing tumor cells less intensely and more naturally (3). *Trametes robiniophila* Murr. (Huaier) has been applied in traditional Chinese medicine for approximately 1600 years (4); however, its antitumor potency has been discovered only in recent decades and is used as a complementary therapy. The major effective ingredient of this officinal fungi has been identified as proteoglycan, which contains 41.53% polysaccharides, 12.93% amino acids, and 8.72% water (5). A number of studies have shown that Huaier extract exerts potential antitumor effects in many tumor types through proliferation inhibition and apoptosis induction (6-11). In addition, a multicenter, randomized clinical trial has indicated that Huaier extract prolonged significantly recurrence-free survival and reduced extrahepatic recurrence rates in HCC patients after curative resection (12). These studies demonstrated that Huaier extract may be a promising treatment of cancers alone or in combination with other drugs. However, the underlying anti-tumor activity and molecular mechanisms of Huaier extract in hepatoblastoma cells are not yet fully understood.

Cell cycle disturbance, leading to uncontrolled cell proliferation, is one of the most common alterations that occur during tumor generation. Therefore, cell cycle arrest is considered to be an effective approach for eliminating tumor cells (13). Two major checkpoints, one at the G<sub>1</sub>/S transition and the other at the G<sub>2</sub>/M transition, regulate cell cycle and, therefore, the expression of molecules that regulate transition through these phases of the cell cycle have been investigated in numerous cell types (14). A general process associated with DNA damage is the activation of cell cycle checkpoints and promotion of cell cycle. Cyclin-dependent kinases (cdks) are evolutionarily conserved proteins that are essential for cell cycle control. Distinct pairs of cyclins regulate the progression through the various stages

of the cell cycle. Among these cyclins, cyclin D1 is regarded as an oncogene and is a vital driver of multiple types of human tumors including breast and squamous cell cancers, B-cell lymphoma, myeloma, and parathyroid adenoma (15). In addition to cyclin D1, mitogen-activated protein kinase (MAPK) superfamily members are also associated with increased proliferation, survival, and apoptosis, serving different roles in cellular responses (16). ERK1/2, p38 MAPK, and JNK/SAPK have also been reported to play central roles in the regulation of cyclin D1 expression (17).

Little is known about the molecular mechanisms responsible for the anti-proliferative properties of Huaier extract, and no studies have investigated the potential role of Huaier in human hepatoblastoma cells. Understanding the role and mechanism of Huaier extract will provide useful information for their possible application in cancer therapy. Therefore, in this study, we aimed to explore the anti-proliferative effect and mechanisms of Huaier extract in hepatoblastoma cells.

## Materials and Methods

**Preparation of Huaier extract.** The electuary Huaier ointment was provided by Qidong Gaitianli Medicine Co., Ltd. (Qidong, Jiangsu, PR China). In total, 2 g of the electuary ointment were dissolved in 20 ml complete medium and sterilized through a 0.22 µm filter to obtain a 100 mg/ml stock solution, which was subsequently stored at -20°C.

**Cell lines and cell culture.** The HepG2 and HuH-6 human hepatoblastoma cell lines were used in this study. They were purchased from the cell bank of RIKEN BRC (Tsukuba, Ibaraki, Japan). The human hepatoblastoma cell line, HuH-6, was cultured in DMEM (#11885-084, GIBCO, Tsu, Mie, Japan) medium supplemented with 10% fetal bovine serum (FBS) (#10100147, GIBCO). The other human hepatoblastoma cell line, HepG2, was cultured in DMEM (#11995-065, GIBCO) medium supplemented with 10% FBS (#10100147, GIBCO). Cells were incubated in a humidified atmosphere at 37°C with 5% CO<sub>2</sub>.

**Antibodies and reagents.** The following antibodies and reagents were used in this study: anti-MEK (#9122, Cell Signaling, Tokyo, Chiyodaku, Japan), anti-ERK1/2 (#9102, Cell Signaling), phospho-MEK (#9121, Cell Signaling), phospho-ERK1/2 (#9106, Cell Signaling), anti-cleaved PARP (#5625, Cell Signaling), anti-PARP (#9532, Cell Signaling), cell cycle regulation kit (#9932, Cell Signaling).

**Cell morphology.** The hepatoblastoma cells were incubated with 2 or 5 mg/ml Huaier extract for 48 h. In order to identify the morphological changes of the hepatoblastoma cells, the cells were observed under an Olympus light microscope (CX31-72C02; Olympus Corporation, Tokyo, Japan), and photomicrographs were captured using an Olympus digital camera (DP72; Olympus Corporation).

**MTT assay.** MTT reagent was obtained from Sigma Aldrich (Tsu, Mie, Japan). Cells (5×10<sup>3</sup>) were seeded in 100 µl medium in 96

wells plates and pre-incubated for 6 h before the addition of the inhibitors. MTT (20 µl, 5 mg/ml) was added into each well. After 3.5 h incubation in a humidified atmosphere at 37°C with 5% CO<sub>2</sub>, the culture media was removed, and DMSO (150 µl) was added. The plates were shaken vigorously for 15 min and the absorbance at 590 nm was measured using multi-spectrophotometer (Viento, Dainippon, Japan). The optical density was used to determine cell viability. The results are expressed as mean±SD from 3 independent experiments.

**Western blotting.** Cellular extracts were obtained as previously reported (18). The proteins (20 µg/lane) were analyzed on 7.5, 10 or 15% sodium dodecyl sulfate–polyacrylamide gel electrophoresis followed by semi-dry transfer to PVDF membrane (Invitrogen, Carlsbad, CA, USA). PVDF membranes were pretreated with 5% non-fat dry milk in TBST containing 0.1% Tween-20 and incubated with primary antibody (1:1000-3000) at 4°C overnight. The membrane was then washed 3 times with TBST and incubated with horseradish peroxidase-conjugated secondary antibody (1:1000-3000) for 1 h at room temperature (28-35°C). To detect phosphorylated proteins, transferred PVDF blots were pretreated with PVDF Blocking Reagent (TOYOBO, Osaka, Japan) for 1 h, and incubated with primary and then with secondary antibody (1:3000-6000) which were diluted with Can Get Signal® Immunoreaction Enhancer Solution (TOYOBO) at room temperature for 1 h. After washing three times again, bound antibodies were detected by using Western Lightening Chemiluminescence Reagent Plus (Perkin Elmer Life Science, Boston, MA, USA), and visualized on LAS-3000 mini (FUJIFILM).

**Cell cycle analysis.** Cell cycle analysis was performed after treatment with/without Huaier extract for 24 h. Cells (2×10<sup>6</sup>) were harvested and fixed in 99.5% ethanol over night at -20°C, followed by incubation with 500 µl propidium iodide (PI) Triton X-100 solution containing RNase A at room temperature (28-35°C) for 30 min in the dark. Then the DNA content was analyzed immediately with FACS, analyzed by using the ModFitLT software.

**Statistical analysis.** Statistical analysis was performed using SPSS (IBM Corporation, Tsu, Mie, Japan). Statistical significance of differences between groups was evaluated using Student's *t*-test and two-way ANOVA. A *p*-value <0.05 was considered to be statistically significant.

## Results

**Huaier extract inhibited proliferation and caused morphological changes of HepG2 and HuH-6 cells.** To evaluate the effect of Huaier extract on HepG2 and HuH-6 hepatoblastoma cells, we measured cell viability using the MTT assay after the cells were treated with various concentrations of Huaier for 24, 48 and 72 h. As shown in Figure 1A and B, Huaier significantly inhibited viability of both HepG2 (Figure 1A) and HuH-6 (Figure 1B) in a dose-dependent manner. HepG2 cells were more sensitive than HuH-6. Treatment with 8 mg/ml of Huaier for 72 h decreased the viability of HepG2 and HuH-6 cells by almost 97% and 72%, respectively. The morphological changes of

Figure 1. Huaier extract suppressed cell viability of HepG2 and HuH-6 cells. The effect of Huaier extract on cell viability was measured by the MTT assay. (A) HepG2 and (B) HuH-6 cells were treated with Huaier extract for 24, 48 and 72 h. Huaier extract significantly inhibited cell viability of both cell lines in a dose-dependent manner. The experiments were performed in triplicate and data is presented as the mean $\pm$ SD of three separate experiments. (C) Phase-contrast images revealing the morphologies of HepG2 and HuH-6 cells prior and after treatment with 4 mg/ml Huaier for 48 h. Magnification 200 $\times$ .

Figure 2. Huaier extract induced S phase accumulation in HepG2 and HuH-6 cells. A. Treatment of HepG2 and HuH-6 cells treated with/without Huaier extract (0, 2, 5 mg/ml) for 24 h was followed by analysis of cell cycle phase distribution, as described in Materials and Methods. Cells were stained with PI for 30 min followed by FACScan flow cytometer analysis. B. HepG2 and HuH-6 cells were incubated in RPMI1640+10% FBS with/without Huaier extract (0, 2, 5 mg/ml) for 24 h. Cyclin D1, Cyclin D3 and actin were detected by western blot. The intensity of Cyclin D1 and Cyclin D3 was quantified by ImageJ. After normalization to actin, the fold increase of Cyclin D1 and Cyclin D3 versus the control was compared. Data represent mean±SD. \*Represents  $p < 0.05$ .

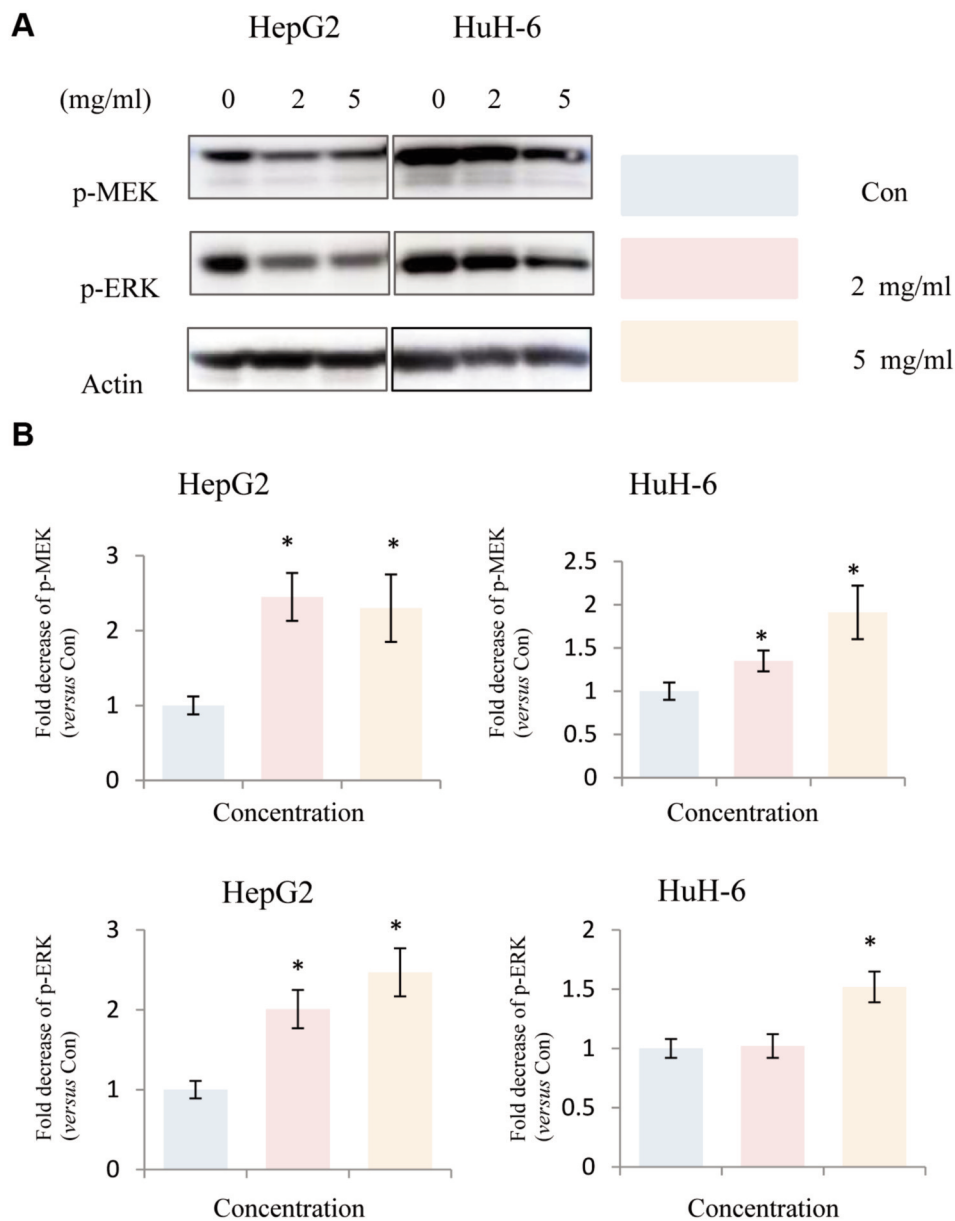

Figure 3. Effect of Huaier extract on MEK/ERK signaling in HepG2 and HuH-6 cells. A. HepG2 and HuH-6 cells were incubated in RPMI1640+10% FBS with/without Huaier extract (0, 2, 5 mg/ml) for 24 h. p-MEK, p-ERK and actin were detected by western blot as described in Materials and Methods. B. The intensity of p-MEK and p-ERK was quantified by ImageJ. After normalization to actin, the fold decrease of p-MEK and p-ERK versus the control was compared. Data represent mean±SD. \*Represents  $p < 0.05$ .

HepG2 and HuH-6 cells after treatment with Huaier for 48 h are shown in Figure 1C. Compared with the untreated cells, the majority of the Huaier-treated HuH-6 cells became enlarged, irregular, spinous and had a vacuolized cytoplasm, while numerous HepG2 cells became extremely elongated and showed the special “wiredrawing” morphology. These morphological changes demonstrated cell damage after Huaier treatment.

Huaier treatment induced S-phase accumulation in HepG2 and HuH-6 cells. To explore the mechanisms responsible for the inhibitory effect, we investigated the impact of Huaier extract on the distribution of cells in the various phases of the cell cycle. As shown in Figure 2A, Huaier extract induced S phase accumulation in HepG2 and HuH-6 cells. The progression from G1 to S phase in mammalian cells is thought to be regulated by D-type cyclins (13, 15). Thus, we

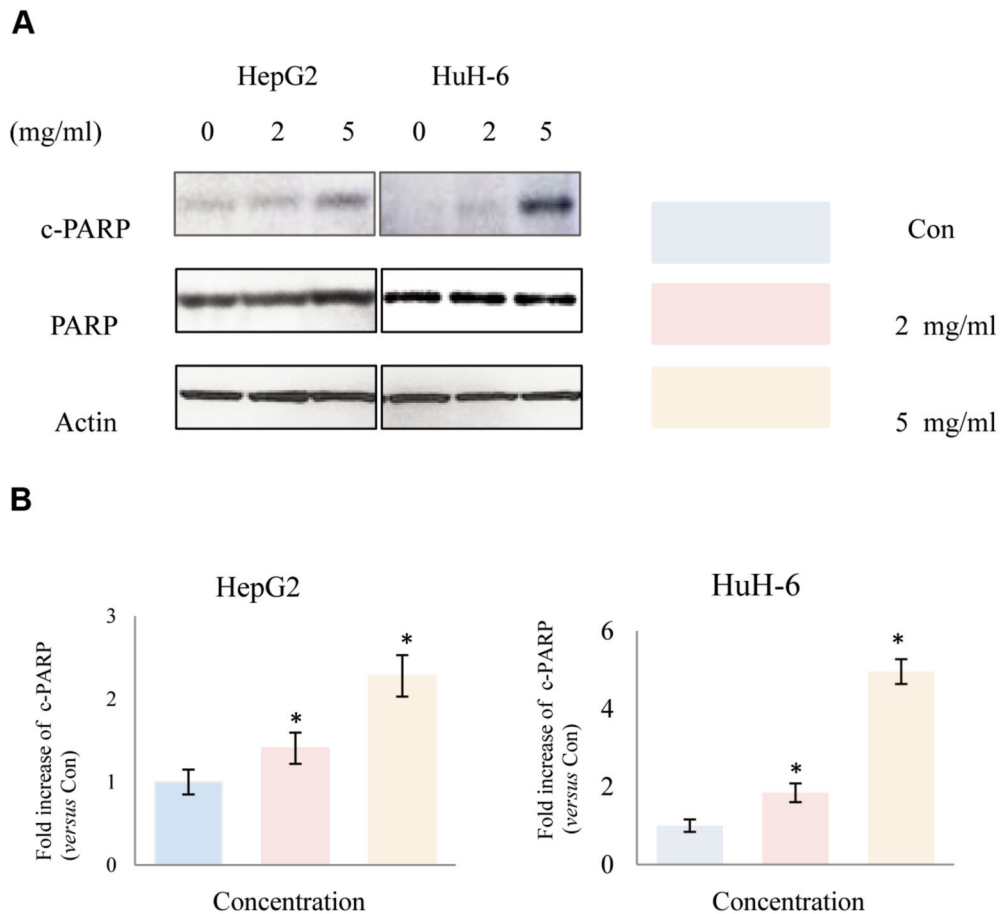

Figure 4. Effect of Huaier extract on apoptosis in HepG2 and HuH-6 cells. A. HepG2 and HuH-6 cells were incubated in RPMI1640+10% FBS with/without Huaier extract (0, 2, 5 mg/ml) for 48 h. Expression of PARP, cleaved PARP and actin were detected by western blot as described in methods and material. B. The intensity of PARP and cleaved PARP was quantified by ImageJ. After normalization to actin, the fold increase of cleaved PARP versus the control was compared. Data represent mean±SD. \*Represents p<0.05.

examined expression of the proteins related to cell cycle regulation by western blot. In HepG2 and HuH-6 cells, cyclin D1 and cyclin D3 were upregulated following treatment with Huaier extract (Figure 2B), consistent with the accumulation of cells in S phase.

*Huaier extract suppressed MEK/ERK signaling in HepG2 and HuH-6 cells.* Since the anti-tumor effect is usually closely correlated with down-regulation of cell survival signaling pathways, we hypothesized that Huaier extract treatment may result in the inhibition of the signaling pathways involved in cell survival. MAPK has been shown to be involved in the induction of cell cycle related cyclin Ds in many types of cancer (17). Given that treatment with Huaier extract upregulated the expression of cyclin D1 and cyclin D3, we examined the expression of MAPK related proteins after treatment of hepatoblastoma cells with Huaier extract. Treatment of HepG2 and HuH-6 cells with different

concentrations of Huaier extract resulted in a significant dose-dependent decrease in the phosphorylation of MEK and ERK in hepatoblastoma cells (Figure 3). This finding indicates that Huaier extract may promote the expression of cyclin D1 and cyclin D3 by inactivating the MEK-ERK signaling pathway.

*Huaier extract induced apoptosis in HepG2 and HuH-6 cells.* It is well known that the induction of apoptosis is a promising target in cancer therapy. To demonstrate the apoptosis effect of Huaier extract, we analyzed the expression of apoptosis related proteins using western blot. After treatment of HepG2 and HuH-6 cells with different concentrations of Huaier extract for 48 h, as shown in Figure 4, expression of cleaved-PARP was significantly upregulated compared to untreated control cells, demonstrating that Huaier extract induced apoptosis in HepG2 and HuH-6 cells.

## Discussion

TCM has gained significant attention following findings on its role in cancer prevention and treatment (19, 20). Huaier extract has been used in China for approximately 1600 years (21). Compared to the conventional chemotherapy and radiotherapy which are not only cytotoxic to tumor cells, but are also harmful to normal cells, Huaier extract, as a complementary antitumor agent, has acquired increasing attention because of its antitumor effects and low toxicity (19, 22). Huaier extract has been investigated in patients and found to provide clinical benefits. Zhang *et al.* have found that Huaier granule could prolong the DFS, reduce serum tumor markers and improve the quality of life of breast cancer patients (23). In the present study, the antitumor effect and underlying mechanisms of Huaier extract in hepatoblastoma cells were investigated.

We obtained data indicating that treatment of hepatoblastoma cells with 0, 2, 4, 8, 16 mg/ml of Huaier extract inhibited their proliferation and induced apoptosis. It was also demonstrated that Huaier extract inhibited cell viability and induced morphological changes to cells. The MTT assay also revealed that the Huaier extract reduced the viability of hepatoblastoma cells in a dose-dependent manner. In addition, certain apoptotic morphological alterations were observed following treatment with Huaier extract, which indicated cell damage.

Previous studies have indicated that Huaier extract induces cell cycle arrest and apoptosis in a number of cell types, such as hepatocarcinoma, melanoma, ovarian cancer and breast cancer cells (24-27). The results from the present study revealed that the proportion of S phase hepatoblastoma cells gradually increased, consistent with the upregulation of the cell-cycle proteins cyclin D1 and cyclin D3. These results suggest that Huaier extract suppresses the proliferation of hepatoblastoma cells through the upregulation of cell cycle proteins to induce cell cycle arrest at the S phase. It is well known that the induction of apoptosis is a promising cancer treatment strategy. Furthermore, we found that treatment of cells with Huaier extract increased apoptosis compared to untreated control cells. It has been shown that many human tumors and cell lines derived from tumor cells display constitutive activation of the MEK/ERK signaling pathway, which regulates apoptosis and cell cycle progression (28). As shown in present study, the phosphorylation of MEK and ERK in hepatoblastoma cells was reduced by Huaier extract. This finding indicates that Huaier extract may induce cell-cycle arrest and apoptosis through inactivation of the MEK-ERK signaling pathway.

In summary, our results showed that Huaier extract could inhibit cell proliferation by inhibiting the MEK-ERK signaling pathway to induce apoptosis and cell-cycle arrest in hepatoblastoma cells. These results contribute to the

understanding of the anticancer activity of Huaier extract. Therefore, Huaier extract may be used as a novel complementary medicine in hepatoblastoma treatment.

## Conflicts of Interest

The Authors have no conflicts of interest to declare regarding this study.

## Authors' Contributions

Xiao-jun Yuan designed the study; Dong-qing Xu performed experiments, analyzed the data and wrote a draft of the manuscript; Masahiro Hirayama and Hidemi Toyoda revised the manuscript.
